JavaScript Embedding
==================

1. As we know JavaScript is available in many **HOST ENVIRONMENTS** and the two most popular are **browser** and **server(Node.js).**

2. Since we are learning Front-end JavaScript our host environment is browser and within the browser JS does need support of HTML to run.

3. This means that for client side JS or Front-end JS or browser based JS we need to embed JS code within HTML page and this can be done in two ways:
 a) Local Embedding : Writing JS code directly inside HTML page
 b) External Embedding : Writing JS code in a separate .js file and then linking it with HTML page

Syntax of Local Embedding
=====================
1.
```html
<html>

   <head>
           <script>
                   // js code
           </script>
   </head>
   <body>
              .............
              ..............
   </body>
</html>
```

Syntax of Local Embedding
=====================
2.
```html
<html>

   <head>
   </head>
   <body>
              .............
              ..............
           <script>
                   // js code
           </script>
   </body>
</html>
```
